TECHNICAL SUMMARY

Electrical Characteristics:

Type of Emission.....	Telephone
Carrier Output.....	1000 Watts
Frequency Range.....	530-1600 KC
Power Supply.....	210/230 Volts, 3 Wire, Single Phase 50-60 Cycle AC
Power Consumption (for 100% modulation).....	5000 Watts
Radio Frequency Stability.....	±10 Cycles
Modulation.....	100% High Level
Audio Input (500-600 ohm source) for 100% modulation.....	Zero Level DB for 1 Milliwatt Reference Level
Average Program Level.....	-5 DB (1 Milliwatt Reference Level)
Audio Frequency Response.....	±1 DB from 30-10,000 Cycles
Audio Distortion (50-7500 Cycles).....	Less than 2½% RMS for 95% Modulation
Noise Level.....	More than 60 DB below 100% Modulation
Output Circuit.....	Designed to feed 70-250 ohm transmission lines
Carrier Shift.....	Less than 3% from 0-100% modulation 50-7500 Cycles

Tube Complement:

Crystal Oscillator.....	6J5
Buffer.....	Class "A" 807
R-F Driver.....	Push-Pull 813A's
R-F Power Amplifier.....	Push-Pull 833A's
First Audio.....	Push-Pull Class "A" 6J7's
Second Audio.....	Push-Pull Class "A" 6J5's
Audio Driver.....	Push-Pull Class "A" 845's
Modulator.....	Push-Pull Class "B" 833A's
R-F Exciter Power Supply.....	350 Volts 200 MA full wave 5U4G
Low Level Audio Power Supply.....	350 Volts 200 MA full wave 5U4G
Modulator Bias Power Supply.....	80 Volts 400 MA full wave 2 - 5U4G's
R-F and Audio Driver Power Supply.....	1500 Volts 425 MA 2 - 866A's
High Voltage Power Supply.....	2750 Volts 1.2 AMP 2 - 575A's

Mechanical Specifications:

Height.....	84 inches
Depth.....	34½ inches
Width.....	48½ inches
Floor Area.....	11½ sq. ft.
Weight.....	2450 pounds

SECTION I

GENERAL DESCRIPTION

This transmitter is designed to operate at any frequency between 530 and 1600 Kc. It will deliver its rated power into a 70 to 250 ohm transmission line and provide reliable high fidelity operation with negligible distortion and carrier noise.

This equipment is operated from a 210/230 volt, 3 wire single phase 50-60 cycle power line. All transformers have 210-220-230 volt taps readily accessible for various power line voltages encountered.

Mechanical Construction. The complete transmitter is assembled into one spacious cabinet in such a way that all components are readily accessible for inspection and service if necessary. Chassis construction is used wherever possible for isolation of circuits and to facilitate servicing. The transmitter is constructed in an inner cabinet with wiring between the walls which is readily accessible by hinged side panels or easily removable front panels making a unit that is neat and rugged yet easily accessible for inspection. Two large doors enclose the rear of the cabinet. Opening of these doors will operate high voltage interlock switches.

CIRCUIT DESIGN

Control Circuits. The control circuits in this transmitter serve to provide convenient operation and adequate protection to the tubes and other components. All power supplies have either fuses or over-load protection. All controls necessary for the operation of this transmitter are located on a recessed panel. On this control panel are six sets of push buttons. On the left are the "Filament Start", "Stop" push buttons which place the transmitter in the stand-by position. In the center are four sets of push buttons that control the reversible motors driving the radio-frequency tuning circuits. On the right are the "Plate Start", "Stop" push buttons controlling the high voltage power supplies. A "Filament" rheostat (7R-1) adjusts all filaments to take care of slight power line voltage changes. The "Plate" rheostat (7R-2) adjusts the power input to the radio-frequency power amplifier to maintain correct carrier level. Also located on the control panel are switches to select crystals and radio-frequency transmission lines feeding the antenna. The neutralizing "R-F Pick-up" jack and "Neutralizing" adjustment are located on the control panel. The liberal use of meters helps facilitate all adjustments. Five meters located on the control panel are in the low power radio-frequency and audio-frequency circuits. Eight large easy to read meters near the top of the cabinet are connected in the modulator, radio-frequency power amplifier and antenna circuits.

Four pilot lights located above the control panel and visible at all times indicate "Filament", "Crystal 1", "Crystal 2" and "Plate".

Power Supply Circuits. A power supply of 350 volts using a 5U4G rectifier assembled on the radio-frequency exciter chassis supplies power to the 6J5 crystal oscillator and 807 buffer amplifier. The audio amplifier power supply

chassis uses a 5U4G rectifier supplying 350 volts to the push-pull 6J7 and 6J5 tubes. A separate filament transformer on this chassis supplies the push-pull 845 tubes. The modulator bias supply uses two 5U4G rectifier tubes supplying a variable voltage to the Class "B" 833A modulator grids and fixed bias of 60 volts for the 813 r-f driver tubes.

Two 575A rectifier tubes supply 2750 volts to the radio-frequency power amplifier and the Class "B" modulator tubes. An intermediate power supply using two 866A rectifiers supplies 1500 volts for the push-pull 813's and push-pull 845 tubes.

Audio-Frequency Circuit. The audio-frequency amplifier consists of four stages of push-pull amplification that has an essentially flat response from 30-10,000 cycles. It is designed for 500/600 ohm balanced line zero level db input (1 milliwatt reference level). The first two push-pull stages consist of 6J7 tubes resistance coupled to push-pull 6J5 tubes and resistance coupled to push-pull 845 driver tubes. A transformer is used between the push-pull 845's and the Class "B" 833A modulator tubes. Negative feedback is connected over the last three stages which greatly improves the frequency response and distortion. The transmitter will work satisfactorily without the feedback network in case some trouble arises. There is ample power available to 100% modulate the transmitter with negligible distortion.

Radio-Frequency Circuit. Excellent frequency stability is attained by the use of temperature controlled, low temperature coefficient crystals connected in the conventional triode oscillator circuit using a 6J5 tube. Vernier frequency control is obtained by an adjustment of capacitors LC-3 or LC-4 (depending on the crystal in use). There are two stages of radio-frequency amplification between the crystal oscillator and the power amplifier. The first radio-frequency amplifier is an 807 tube Class "A" which reduces the possibility of any frequency drift due to loading of the crystal oscillator tube. The second radio-frequency amplifier consists of two 813 tubes in push-pull which have more than sufficient available power to drive the 833A power amplifier tubes. There are three tuned tank circuits in this transmitter and a variable radio-frequency line pick-up coil.

INSTALLATION

Location and Connections. The location of the transmitter should be carefully selected and provisions made for the external connections. There should be ample space around the cabinet to allow for plenty of air circulation and to facilitate inspection and servicing when necessary. It is important that the transmitter cabinet be securely grounded. For this purpose, a heavy copper strip connected to a good ground or buried counterpoise is recommended. Provisions for the antenna feed lines are at the top of the cabinet.

The transmitters are ordinarily shipped with the stationary contacts of 2K-1 wired to the two feed through insulators in the top of the cabinet. One side of the antenna coupling coil 2L-5 is grounded directly to the top of the cabinet. The transmission line can be connected to one insulator and the

ground connection. If desired, a dummy antenna load may be connected to the other insulator and ground. If it is desirable to run the coaxial cables directly into the transmitter, they may be connected through the two holes directly above 2K-1 and the internal wiring changed for this type of installation. The three wire single phase 210-230 volt a-c line can be brought in through holes in the rear or bottom of the cabinet and connected to terminal block 6TB-1 located on the left side of the transmitter. Access to this large terminal block is made by loosening the four one-half turn fasteners along the rear of the side panel and opening it like a door. Terminal block 6TB-2 has provisions for connecting wires to 4 remotely located push buttons that will control the power on-off to the transmitter.

The station frequency monitor is connected through a 70 ohm line to terminals G and H on terminal block 1TB-2 located on the radio-frequency exciter chassis. On terminal block 6TB-7 (located inside the cabinet near the top on the left side) terminals "A" - "B" are for audible monitoring purposes and terminals "C" - "D" should be connected to the station modulation monitor through a 70 ohm line. The wiring to the monitoring equipment can be brought in through holes in the rear of the transmitter base. A balanced audio-frequency line should be brought through the bottom or rear holes and connected to 3TB-1 terminals "A", "B" and "C". Terminal "B" is the ground or shield connection.

Preliminary Adjustments. As soon as power is applied to terminal block 6TB-1, the crystal indicator lights labeled "Crystal 1" and "Crystal 2" should light. These lights show when the crystal ovens are heating and will turn on and off after the crystal ovens have reached their operating temperature. Press the "Filament Start Button". This closes the main power contactor relay 6K-6. This contactor is protected by thermo-overload switches 6S-1 and 6S-2. Adjust the "Filament" rheostat until the a-c "Filament" voltmeter reads 10 volts. This "Filament" rheostat (7R-1) should now be at approximately 50% rotation. The "Filament" rheostat controls all the filaments. All tubes should now have their rated filament voltages; if not, the a-c power line should be measured and the taps on all the transformers changed to correspond to the line voltage available at 6TB-1.

The crystal frequency should be adjusted to zero beat with the frequency monitor. This consists of adjusting the condensers 1C-3 or 1C-4 located directly beneath the crystal in use. Note the readings on the meters labeled the "Oscillator Plate", "Buffer Plate" and "R.F. Driver Grid". These should be approximately the values shown in the table on meter readings.

Adjust 5R-3 for a reading of 60 volts between terminal E of 5TB-1 and chassis.

Adjust 5R-1 and 5R-2 until there is approximately minus 70 volts on each of the 833A modulator tubes. This can be measured directly on each grid or on terminals G and H of terminal block 5TB-1. Place switch 6S-5 in the off position, this removes the high voltage from both the power amplifier and modulator tubes. This places the transmitter in readiness for neutralizing. At this time be sure the 575A and 866A rectifier tubes have been preheated long enough to drive all mercury vapor from their filaments. Press the plate start button. This will close contactor relay 6K-5 providing the following has occurred:

- (1) The rear doors are closed, operating interlock switches 6S-3, 6S-4.
- (2) The modulator bias supply voltage has closed relay 6K-3.
- (3) No excessive overload is operating the overload relays 6K-1, 6K-7.
- (4) The time delay relay 6K-4 has operated.

The 813 grid and plate circuits should be tuned by pressing either the upper or lower push button depending on which direction it is necessary to adjust for maximum "Final Grid" current. Note the reading of the "R.F. Driver Plate" and "Final Grid" meters. These readings should be approximately the values given in the table on meter readings. Insert in the "R.F. Pick-up" jack located on the control panel a neutralizing indicator which may be a 1.5 volt 60 ma pilot light or vacuum tube voltmeter. Adjust the "833 Plate Tuning" for maximum reading on the r-f indicator. The "Neutralizing Condenser" should be adjusted with a screw driver for minimum reading on the r-f indicator. This procedure should be repeated until the lowest possible indication is reached on the r-f pick-up indicator. The "813 Plate Tuning" should be checked for maximum "Final Grid" meter reading. The "Final Grid" meter should be adjusted for approximately 160 ma. Adjusting 6R-3 located near the 813 chassis adjusts the 813's screen voltage and regulates the reading of the "Final Grid" meter. The transmitter should now be neutralized and sufficient grid power applied to the 833A R.F. tubes.

Remove the plate power by pushing the red button "Plate Stop". The switch 6S-5 should be placed in the on position. Either the antenna or some dummy r-f load should be connected to the transmitter. Press the "Plate On" button and adjust "833 Plate Tuning" for minimum "Final Plate" meter current reading. Adjust "Plate" rheostat 7R-2 until the "Final Plate" voltmeter reads 2500 volts. This rheostat should now be at approximately 50% rotation. It may be necessary to change the primary tap on 6T-4 to bring the voltage within the prescribed setting of the rheostat. Adjust the "Antenna" tuning until the "Final" current meter reads 560 ma. These values of voltage and current are approximately correct for 1 KW output.

The "Modulation Plate" current meters should be adjusted for a static reading of 50 ma by means of 5R-1 and 5R-2 located on the modulation bias supply chassis.

An audio signal at zero level db should be fed into terminals "A", "B" and "C" of terminal board 3TB-1 and the signal noted on the audio monitor and modulation monitor. Radio-frequency driving power can be adjusted by means of resistor 6R-3 near the 813 chassis. Audio-frequency driver bias is adjustable by resistor 4R-2 located beneath the audio power supply chassis, and should be adjusted to 195 volts. The plate voltage for the audio-frequency driver tubes should be 1450 volts adjustable by the slider on resistor 6R-5 near the audio amplifier chassis.

The overload relay 6K-1 is adjusted by resistor 6R-8 located beneath the relay. This adjustment should be such that the normal current drawn by the Class "B" modulator and final amplifier tubes will not close 6K-1 relay and open

the plate power contactor 6K-5.

OPERATION

To start the transmitter, press the "Filament Start" button located on the control panel. The following approximate meter readings should now be noted:

P.A. FILAMENT.....	10 VOLTS
OSCILLATOR PLATE.....	8 MA
BUFFER PLATE.....	55 MA
R.F. DRIVER GRID.....	5 MA

After 30 seconds or more have elapsed, press the "Plate Start" button. The following approximate meter readings should be noted.

R.F. DRIVER PLATE.....	110 MA
A.F. DRIVER PLATE.....	160 MA
MODULATOR PLATE.....	50 MA
MODULATOR PLATE.....	50 MA
FINAL GRID.....	160 MA
FINAL PLATE.....	2500 VOLTS
FINAL PLATE.....	560 MA
R.F. LINE.....	DEPENDS UPON ANTENNA
ANTENNA.....	DEPENDS UPON ANTENNA DESIGN

The transmitter is now ready to operate and audio modulation may be applied.

MAINTENANCE

Once this equipment is properly installed, it will provide reliable trouble-free operation for long periods of time.

It is important that the transmitter be kept clean and free of dust, particularly the variable condensers and insulators.

A regular check should be made of the tubes in the transmitter. Any tube showing impaired filament emission should be replaced. Care should be taken with mercury filled tubes to see that they are kept in an upright position and that no mercury is splashed on the tube elements. Tubes of this type that have been shaken or tipped should be preheated before being placed into service. Tube prong and socket contacts should be given periodic inspection.

The equipment should be inspected periodically for poor contacts and loosened switch connections. Connections and contacts should be cleaned regularly and all mechanical connections, such as bolts, nuts, and screws should be kept tight.

The gear train and tuning motors should be greased every two years.

VACUUM TUBE CURRENT METER
MODEL RCM-10

TECHNICAL SUMMARY

Specifications

Frequency Range..... 540-1600 Kc

Scale..... Linear

Power..... 100-200 V 50-60 Cycles

Accuracy..... 2% when used with Weston type 301 meter.
1% when used with Weston type 741 meter.

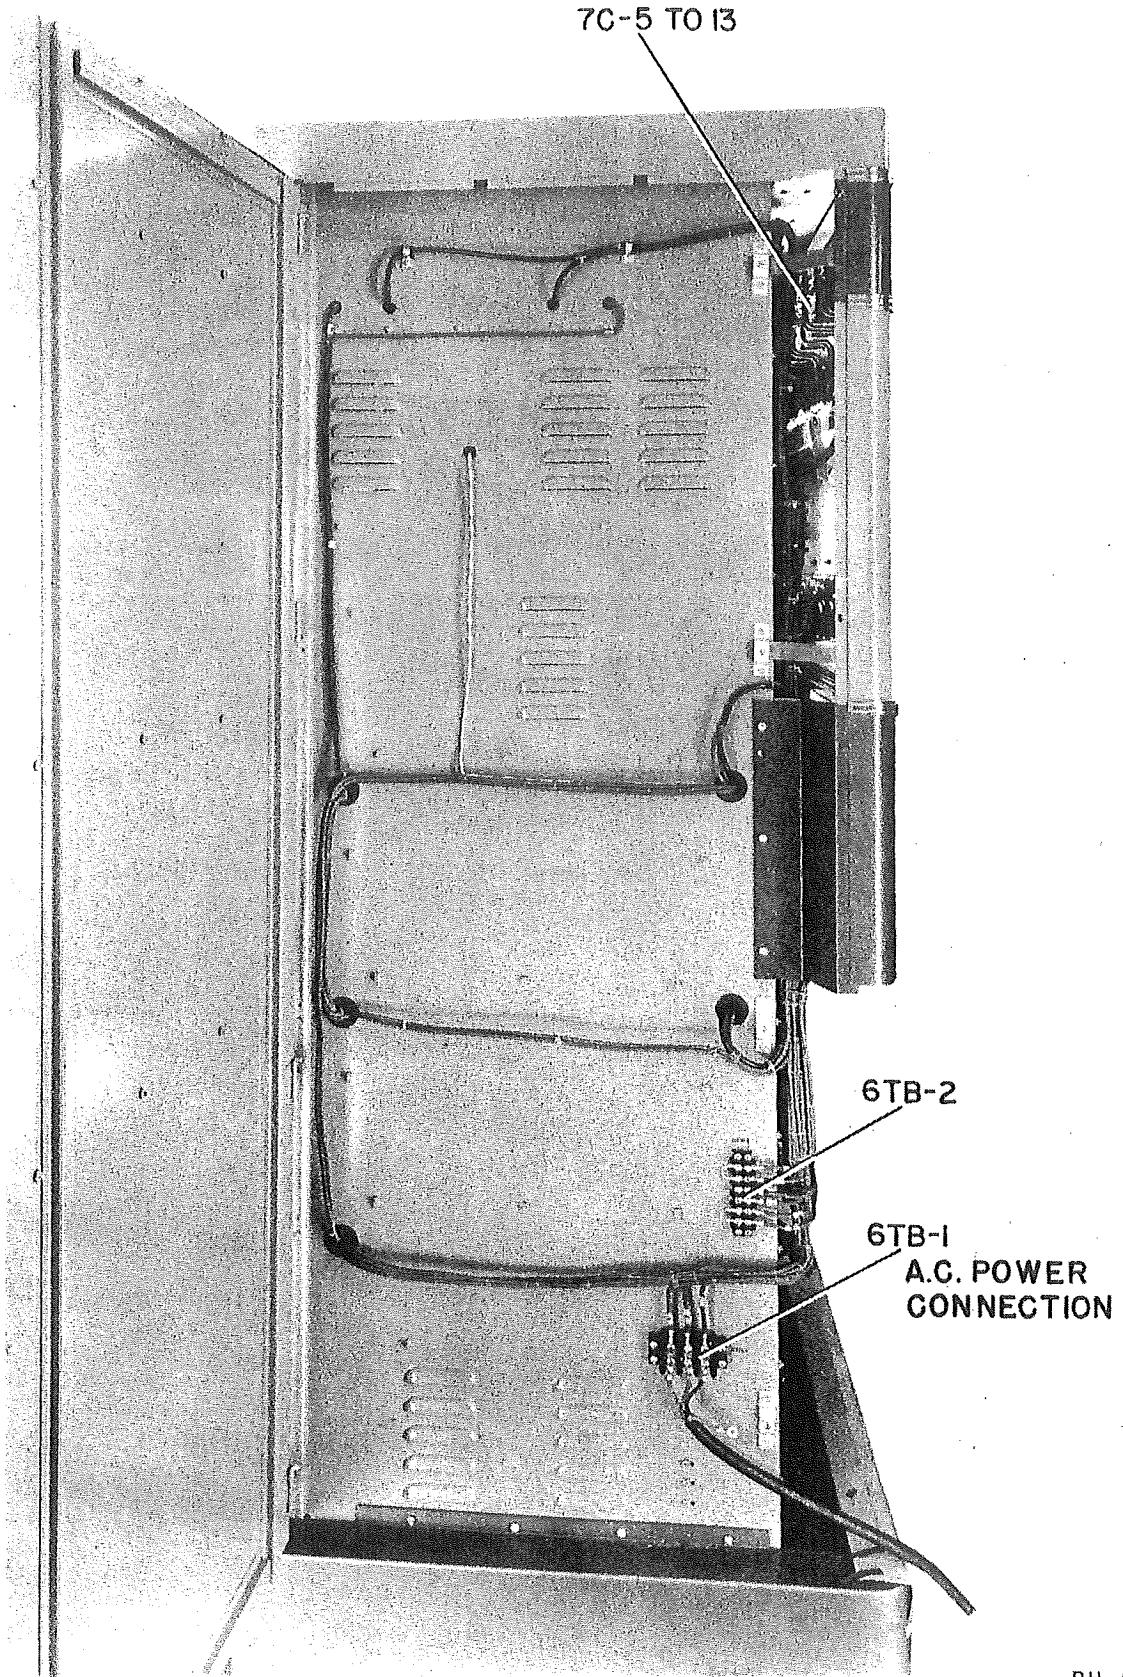

GENERAL INFORMATION

The RCM-10 Vacuum Tube Current Meter comprises a type 6AL5 tube, filament transformer, coils and other associated parts on a bakelite panel and mounted in metal housing. It is intended for use with the linear remote meters in existing transmitter equipment.

The Vacuum Tube Current Meter supplied with the RA-250 or RA-1000 transmitters for use as a line current meter is adjusted at the factory for the customer's specified frequency. Its accuracy is well within the 2% tolerance required by F.C.C. regulations.

When this unit is used as a remote reading antenna current meter in the Model RT-1000 Antenna Tuning Unit it should be adjusted in agreement with the thermocouple antenna current meter (M-13) which is part of RT-1000. The coarse adjustment of the remote reading meter can be made by varying rheostat 8R-2 located on RCM-10 next to the 6AL5 tube. This rheostat is provided with a shaft lock. The fine adjustment should be made by varying the remote meter adjustment potentiometer. This adjustment is located on the transmitter behind the antenna current meter and is accessible from the right hand side door.

The RCM-10 Meter is intended to read only average line or antenna current and it is provided with a suitable time constant circuit to prevent carrier modulation from being indicated. The meter will therefore not follow the modulated carrier and it can be read at any time for making log entries.
